and Belle collaboration

We present a study of hadronic tau decays, especially decay into three-hadron final states with kaon(s), using more than 500fb^{-1} of data collected with the Belle detector at the KEKB asymmetric-energy e^+e^- collider. We measure the branching ratios both inclusively and exclusively while considering the intermediated states of $K^*(892)^0$. The following results are obtained: $\mathcal{B}(\tau^- \rightarrow K^- \pi^+ \pi^- \nu_\tau) = (3.25 \pm 0.02^{+0.16}_{-0.15}) \times 10^{-3}$, $\mathcal{B}(\tau^- \rightarrow K^- K^+ \pi^- \nu_\tau) = (1.53 \pm 0.01 \pm 0.06) \times 10^{-3}$, $\mathcal{B}(\tau^- \rightarrow K^- K^+ K^- \nu_\tau) = (2.60 \pm 0.23 \pm 0.10) \times 10^{-5}$ and $\mathcal{B}(\tau^- \rightarrow K^*(892)^0 K^- \nu_\tau) = (1.56 \pm 0.02 \pm 0.09) \times 10^{-3}$. We also measure the mass and width of the $K^*(892)^0$ resonance as $M_{K^*(892)^0} = 895.10 \pm 0.27 \pm 0.31 \text{ MeV}/c^2$ and $\Gamma_{K^*(892)^0} = 47.23 \pm 0.49 \pm 0.79 \text{ MeV}$, which are the first results obtained using τ decay.

1. Introduction

Hadronic τ decays with kaons provide a good probe for the strange sector of a weak charged current. The decays of $\tau^- \rightarrow K^- \pi^+ \pi^- \nu_\tau$ and $\tau^- \rightarrow K^- K^+ \pi^- \nu_\tau$ are Cabibbo suppressed decay. From the study of these modes, one can determine the strange quark mass and the CKM matrix of V_{us} . On the other hand, the decay of $\tau^- \rightarrow K^- K^+ \pi^- \nu_\tau$, including $\tau^- \rightarrow K^{*0} K^- \nu_\tau$ occurs through a vector and axial-vector current. Therefore, it is sensitive to the Wess-Zumino anomaly for $\text{SU}(3)_L \times \text{SU}(3)_R$.

This study was performed at the KEKB asymmetric-energy e^+e^- collider [1] with the Belle detector [2]. The KEKB collider has realized the world-highest luminosity of $1.7 \times 10^{34} \text{cm}^{-2} \text{s}^{-1}$. The Belle detector shows good particle identification (PID) ability. PID is based on the energy deposit and shower shape in the electromagnetic calorimeter, the momentum and dE/dX measured in the drift chamber, the particle range in the muon chamber, the light yield in the aerogel threshold Cherenkov counters, and the particle's time-of-flight from the TOF counter [3]. The efficiency and fake rate for kaon identification is about 90% and 6%, respectively.

In following studies, the detection efficiency for each signal mode and the amount of the background (BG) contribution are estimated from the data itself as well as Monte Carlo (MC) simulations. To generate signal events as well as τ -decay originated background, the KKMC program [4] is used. The background from the $e^+e^- \rightarrow q\bar{q}$ process is simulated using EvtGen [5]. The detector response is simulated by a GEANT3 [6] based program.

2. Study of $\tau^- \rightarrow K^- \pi^+ \pi^- \nu_\tau$

In the analysis, we select 3-1 topology events divided by the thrust axis, and require no energetic photon on the 3-prong signal side. The large amount of $q\bar{q}$ and two-photon BG processes are removed by requiring the missing energy to be due to the τ neutrinos in the signal candidates, and the lepton on the tag side. We apply the kaon identification to the charged particles on the signal side and categorize the final state. The main BG source after event selection is the τ decays with a mis-identified pion as a kaon. Therefore, in order to suppress the systematic uncertainty, we analyze the cross-feed BG events simultaneously.

Figures 1 show the invariant mass distributions of $K^- \pi^+ \pi^-$, $K^- K^+ \pi^-$ and $K^- K^+ K^-$ for samples with the corresponding PID selection, using data of 669fb^{-1} . The contribution of $q\bar{q}$ and two-photon processes are found to be negligible from a MC estimation. The decays of $\tau^- \rightarrow K^- \pi^+ \pi^- \nu_\tau$ and $\tau^- \rightarrow K^- K^+ K^- \nu_\tau$ have large BG contributions due to a mis-identification of kaons. On the other hand, the result of $\tau^- \rightarrow K^- K^+ \pi^- \nu_\tau$ shows less BG because of a relatively high branching fraction.

Figure 1: Invariant mass distributions of (a) $K^-\pi^+\pi^-$, (b) $K^-K^+\pi^-$ and (c) $K^-K^+K^-$. Cross points are data. Histograms indicate the BG distributions estimated by MC for $\tau^- \rightarrow \pi^-\pi^+\pi^-\nu_\tau$ (open), $\tau^- \rightarrow K^-\pi^+\pi^-\nu_\tau$ (light gray), $\tau^- \rightarrow K^-K^+\pi^-\nu_\tau$ (hatched) and other BG modes (dark gray).

Reconstructed decay mode	Generated decay mode			
	$\tau \rightarrow \pi\pi\pi\nu$	$\tau \rightarrow K\pi\pi\nu$	$\tau \rightarrow KK\pi\nu$	$\tau \rightarrow KKK\nu$
$\pi\pi\pi\nu$	0.23	0.076	0.023	7.3×10^{-3}
$K\pi\pi\nu$	0.012	0.172	0.049	0.023
$KK\pi\nu$	4.0×10^{-5}	4.7×10^{-3}	0.129	0.060
$KKK\nu$	2.8×10^{-7}	1.4×10^{-5}	2.8×10^{-3}	0.094

Table I: Summary of the efficiencies and fake rates.

Considering the cross-feed contributions between $\tau^- \rightarrow \pi^-\pi^+\pi^-\nu_\tau$, $K^-\pi^+\pi^-\nu_\tau$, $K^-K^+\pi^-\nu_\tau$ and $K^-K^+K^-\nu_\tau$, we evaluate the branching ratios (BR) by solving the relation of the number of events using a matrix of efficiencies and fake rates, given in Table I. The correlation matrix and the number of other BG events are evaluated by using MC samples.

With the normalization correction by leptonic τ decays and a systematic error evaluation, we obtain a preliminary result of BR for $\tau^- \rightarrow K^-\pi^+\pi^-\nu_\tau$ as $\mathcal{B} = (3.25 \pm 0.02(\text{stat.})_{-0.15}^{+0.16}(\text{sys.})) \times 10^{-3}$, together with $\mathcal{B}(\tau^- \rightarrow K^-K^+\pi^-\nu_\tau) = (1.53 \pm 0.01(\text{stat.}) \pm 0.06(\text{sys.})) \times 10^{-3}$ and $\mathcal{B}(\tau^- \rightarrow K^-K^+K^-\nu_\tau) = (2.60 \pm 0.23(\text{stat.}) \pm 0.10(\text{sys.})) \times 10^{-5}$. The dominant systematic uncertainty is an estimation of the track-finding efficiency, 3.2%. Our result is consistent with the world average in PDG2006 [7].

3. Study of $\tau^- \rightarrow K^*(892)^0 K^-\nu_\tau$

We study $\tau^- \rightarrow K^{*0}K^-\nu_\tau$ with data of 545fb^{-1} by requiring the decay $K^{*0} \rightarrow K^+\pi^-$ exclusively. The signal yield is evaluated using the invariant mass distribution of $K^+\pi^-$ with an additional selection of the K^{*0} momentum, $p_{K^{*0}}^{CM} > 1.5\text{GeV}/c$, and the $K^{*0}K^-$ system momentum, $p_{K^{*0}K}^{CM} > 3.5\text{GeV}/c$, in the center-of-mass (CM) system. After all selections, 5.1×10^4 events remain, as shown in Fig. 2(a). A clear $K^*(892)^0$ peak can be seen.

The dominant BG is from other τ decay modes. The largest component, composing $\sim 80\%$ of the BG, arises from $\tau^- \rightarrow K^-\pi^+\pi^-\pi^0\nu_\tau$ and $\tau^- \rightarrow \pi^-\pi^+\pi^-\pi^0\nu_\tau$ through kaon mis-identification and an undetected π^0 . We evaluate the contamination in the $K^{*0}K^-\nu_\tau$ samples, from data samples by replacing the kaon selection by the pion, and taking into account the PID fake rate. Another $\sim 20\%$ of BG is from $\tau^- \rightarrow \phi K^-\nu_\tau$, $K^-K^+\pi^-\pi^0\nu_\tau$ (excluding K^{*0}), $\phi\pi^-\nu_\tau$ and non-resonant $K^-K^+\pi^-\nu_\tau$, and is estimated by MC.

A possible peaking BG is $\tau^- \rightarrow K^*(892)^0 K^-\pi^0\nu_\tau$; however, this has not been measured yet. In order to measure the BR, $\mathcal{B}(\tau^- \rightarrow K^*(892)^0 K^-\pi^0\nu_\tau)$, we apply the same criteria as that for the $K^{*0}K^-\nu_\tau$, but with additional requirements of π^0 . Figure 2(b) shows the $K^+\pi^-$ mass distribution for $\tau^- \rightarrow K^{*0}K^-\pi^0\nu_\tau$. The large peaking BG is from $\tau^- \rightarrow K^{*0}K^-\nu_\tau$ with fake photons due to a hadronic shower in the calorimeter. By applying a fit with

Figure 2: Invariant mass distributions of $K^+\pi^-$ for the selection of (a) $\tau^- \rightarrow K^{*0}K^-\nu_\tau$ and (b) $\tau^- \rightarrow K^{*0}K^-\pi^0\nu_\tau$. The solid curve shows the fitted result. In figure (a), the dashed, dot-dashed and dotted curves indicate the spectra of the interference term, the inverse of interference term and the non-resonant term, respectively. In figure (b), the dotted and dash-dotted curves indicate $K^{*0}K^-\nu_\tau$ contamination and the non- K^{*0} BG.

the Breit-Wigner (BW) function for the $K^*(892)^0$ yield and the landau function for combinatorial BG, we obtain a signal yield of 129 ± 25 events after subtracting the peaking BG's of 114 ± 7 events. The signal efficiency is 0.54%. As a result, we obtain the first measurement of the BR, $\mathcal{B}(\tau^- \rightarrow K^*(892)^0 K^-\pi^0\nu_\tau) = (2.39 \pm 0.46 \pm 0.26) \times 10^{-5}$.

After the BG evaluation, we perform a fit to the $K^+\pi^-$ mass distribution, with the following function: $N_{\text{data}}(M_{K\pi}) = F(M_{K\pi})|\alpha A_{BW}(M_{K\pi}) + \beta A_{NR}(M_{K\pi})e^{i\phi}|^2 + N_{\text{incoh}}(M_{K\pi})$, where $M_{K\pi}$ is the invariant mass of $K^+\pi^-$, $F(M_{K\pi})$ is the phase space and kinematical factor, $A_{BW}(M_{K\pi})$ is the BW function for $K^*(892)^0$, considering the spin, parity and damping factor discussed in the LASS [8] and FOCUS [9]. The term $A_{NR}(M_{K\pi})$ is the non-resonant $K^-K^+\pi^-\nu_\tau$ scalar amplitude, $A_{NR}(M_{K\pi}) = (M_{K\pi}/q) \sin \delta_{\text{LASS}} e^{i\delta_{\text{LASS}}}$, where q is the momentum in the $K^+\pi^-$ center of mass and δ_{LASS} is the phase-shift, given by LASS [8] and FOCUS [9]. The term $N_{\text{incoh}}(M_{K\pi})$ is the incoherent continuum and peaking BG's. The free parameters in the χ^2 -fits are α , β , the $K^*(892)^0$ mass ($M_{K^*(892)^0}$), width ($\Gamma_{K^*(892)^0}$), and the relative phase, ϕ .

We obtain the fit result as shown in Fig. 2(a) and the BR of $\mathcal{B}(\tau^- \rightarrow K^*(892)^0 K^-\nu_\tau) = (1.56 \pm 0.02 \pm 0.09) \times 10^{-3}$ with a non-resonant $K^-K^+\pi^-\nu_\tau$ BR of $(5.76 \pm 0.59 \pm 2.04) \times 10^{-5}$. The dominant systematic uncertainty is the errors of the track-finding and the PID efficiencies. We have measured $\mathcal{B}(\tau^- \rightarrow K^{*0}K^-\nu_\tau)$ in 5.9% precision, which is the most precise measurement ever obtained. The non-resonant $K^-K^+\pi^-\nu_\tau$ contribution is $(5.58 \pm 0.57)\%$, which agrees well with the FOCUS result of $(5.30 \pm 0.74^{+0.99}_{-0.96})\%$. The mass and width of $K^*(892)^0$ are obtained as $M_{K^*(892)^0} = 895.10 \pm 0.27 \pm 0.31 \text{ MeV}/c^2$ and $\Gamma_{K^*(892)^0} = 47.23 \pm 0.49 \pm 0.79 \text{ MeV}$. Those are the first results using τ decay, and are consistent with the result of FOCUS experiment [9].

4. Summary

We have studied hadronic tau decays to the final state with three charged hadrons using $\sim 5 \times 10^8$ τ -pairs. We evaluate the BR of $\tau^- \rightarrow K^-\pi^+\pi^-\nu_\tau$, $K^-K^+\pi^-\nu_\tau$ and $K^-K^+K^-\nu_\tau$, simultaneously, in order to reduce the systematic uncertainty of the cross-feed BG's, and obtain the preliminary result as follows:

$$\mathcal{B}(\tau^- \rightarrow K^-\pi^+\pi^-\nu_\tau) = (3.25 \pm 0.02^{+0.16}_{-0.15}) \times 10^{-3}, \quad (1)$$

$$\mathcal{B}(\tau^- \rightarrow K^-K^+\pi^-\nu_\tau) = (1.53 \pm 0.01 \pm 0.06) \times 10^{-3}, \quad (2)$$

$$\mathcal{B}(\tau^- \rightarrow K^-K^+K^-\nu_\tau) = (2.60 \pm 0.23 \pm 0.10) \times 10^{-5}. \quad (3)$$

These results are consistent with the PDG average [7].

We study $\tau^- \rightarrow K^- K^*(892)^0 \nu_\tau (\rightarrow K^- K^+ \pi^- \nu_\tau)$ and perform a fit to the $K^*(892)^0$ mass distribution by considering the interference between the BW and the non-resonant amplitudes. We also measure the BR of $\tau^- \rightarrow K^- K^{*0} \pi^0 \nu_\tau$. The following BR's, mass and width of $K^*(892)^0$ are obtained:

$$\mathcal{B}(\tau^- \rightarrow K^*(892)^0 K^- \nu_\tau) = (1.56 \pm 0.02 \pm 0.09) \times 10^{-3}, \quad (4)$$

$$\mathcal{B}(\tau^- \rightarrow K^*(892)^0 K^- \pi^0 \nu_\tau) = (2.39 \pm 0.46 \pm 0.26) \times 10^{-5}, \quad (5)$$

$$M_{K^*(892)^0} = 895.10 \pm 0.27 \pm 0.31 \text{ MeV}/c^2, \quad (6)$$

$$\Gamma_{K^*(892)^0} = 47.23 \pm 0.49 \pm 0.79 \text{ MeV}. \quad (7)$$

The high statistical data enable us to measure BR precisely as well as the $K^*(892)^0$ mass and width for the first time using τ decays.
